You are able to configure the program to use more than one display monitor 91bb86ccfa

This software is designed for the assessment of working memory by means of digit span. It has two modes, both implemented on the fly. The first one provides: The history mode (that can be called without arguments) that enables one to see the results of the last three digit spans. The second one (that can be called with an argument) performs a series of digit spans (optionally from an autodefining number, a file, the network, etc) and provides a detailed analysis of these performances. The analyses can be summarized in the following tables: memory totals [number of items correctly recalled in the whole test] time totals [time to correctly recall the items] total recall [number of items correctly recalled in a fixed number of spans] mean span mean recall mean time percentage of span repetitions standard error of the mean number of spans that did not match the theoretical distribution (second mode) number of spans that did not match the empirical distribution (second mode) Tests are called from the menu option "Run" from the menu "Analysis". The present version of the software can be downloaded from the MIT website.
