Visualisation of the circulatory system as described in the ancient Greek science of midwifery. The discovery of the anatomy of the human body and the comprehension of its circulatory system was one of the decisive steps in the progress of medicine. Nowadays it is of clinical importance that the circulation of blood can be visualised in a direct way. To provide an overview of the techniques available for visualisation of the circulation of blood in the human body in which molecular imaging plays a major role. Methodologies for direct visualisation of the circulatory system at molecular level are not new. However, until recently the major barrier to their routine use in medicine and clinical research has been the lack of clear understanding of the physical and physiological effects of the reagents used and the lack of sophisticated patient monitoring systems. Apart from this problem, other factors have hampered the acceptance of these methods in routine clinical practice. In recent years the development of new vascular tracers has provided both improved metabolic imaging agents and new methods for direct visualisation of the blood vessels. Unfortunately, these techniques only allow the investigation of the regional circulation in the brain and the heart. Recent developments in molecular imaging has offered new opportunities for the further development and improvement of these methods. The ability to see where and how biological processes take place in the body in an in vivo setting is of paramount importance for the further advance of medicine.
